13	Self-documenting code: Chapter 32
14	THIS CHAPTER TURNS TO AN AESTHETIC ASPECT of computer pro-
15	gramming—the layout of program source code. The visual and intellectual en-
16	joyment of well-formatted code is a pleasure that few nonprogrammers can ap-
17	preciate. But programmers who take pride in their work derive great artistic sat-
18	isfaction from polishing the visual structure of their code.
19	The techniques in this chapter don't affect execution speed, memory use, or
20	other aspects of a program that are visible from outside the program. They affect
21	how easy it is to understand the code, review it, and revise it months after you
22	write it. They also affect how easy it is for others to read, understand, and mod-
23	ify once you're out of the picture.
24	This chapter is full of the picky details that people refer to when they talk about
25	"attention to detail." Over the life of a project, attention to such details makes a
26	difference in the initial quality and the ultimate maintainability of the code you
27	write. Such details are too integral to the coding process to be changed effec-
28	tively later. If they're to be done at all, they must be done during initial construc-
29	tion. If you're working on a team project, have your team read this chapter and
30	agree on a team style before you begin coding.

You might not agree with everything you read here. But the point is less to win your agreement than to convince you to consider the issues involved in formatting style. If you have high blood pressure, move on to the next chapter. It's less controversial.

31.1 Layout Fundamentals

This section explains the theory of good layout. The rest of the chapter explains the practice.

Layout Extremes

Consider the routine shown in Listing 31-1:

Listing 31-1. Java layout example #1.

CODING HORROR /* Use the insertion sort technique to sort the "data" array in ascending order. This routine assumes that data[firstElement] is not the first element in data and that data[firstElement-1] can be accessed. */ public void InsertionSort(int[] data, int firstElement, int lastElement) { /* Replace element at lower boundary with an element guaranteed to be first in a sorted list. */ int lowerBoundary = data[firstElement-1]; data[firstElement-1] = SORT_MIN; /* The elements in positions firstElement through sortBoundary-1 are always sorted. In each pass through the loop, sortBoundary is increased, and the element at the position of the new sortBoundary probably isn't in its sorted place in the array, so it's inserted into the proper place somewhere between firstElement and sortBoundary. */ for (int sortBoundary = firstElement+1; sortBoundary <= lastElement; sortBoundary++) { int</pre> insertVal = data[sortBoundary]; int insertPos = sortBoundary; while (insertVal < data[insertPos-1]) { data[insertPos] = data[insertPos-1]; insertPos = insertPos-1; } data[insertPos] = insertVal; } /* Replace original lower-boundary element */ data[firstElement-1] = lowerBoundary; } The routine is syntactically correct. It's thoroughly commented and has good variable names and clear logic. If you don't believe that, read it and find a mistake! What the routine doesn't have is good layout. This is an extreme example, headed toward "negative infinity" on the number line of bad-to-good layout. Listing 31-2 is a less extreme example:

Listing 31-2. Java layout example #2. 61 **CODING HORROR** /* Use the insertion sort technique to sort the "data" array in ascending 62 order. This routine assumes that data[firstElement] is not the 63 64 first element in data and that data[firstElement-1] can be accessed. */ public void InsertionSort(int[] data, int firstElement, int lastElement) { 65 /* Replace element at lower boundary with an element guaranteed to be first in a 66 67 sorted list. */ 68 int lowerBoundary = data[firstElement-1];

© 1993-2003 Steven C. McConnell. All Rights Reserved. H:\books\CodeC2Ed\Reviews\Web\31-LayoutAndStyle.doc

69	<pre>data[firstElement-1] = SORT_MIN;</pre>
70	/* The elements in positions firstElement through sortBoundary-1 are
71	always sorted. In each pass through the loop, sortBoundary
72	is increased, and the element at the position of the
73	new sortBoundary probably isn't in its sorted place in the
74	array, so it's inserted into the proper place somewhere
75	between firstElement and sortBoundary. */
76	for (
77	<pre>int sortBoundary = firstElement+1;</pre>
78	<pre>sortBoundary <= lastElement;</pre>
79	sortBoundary++
80) {
81	<pre>int insertVal = data[sortBoundary];</pre>
82	<pre>int insertPos = sortBoundary;</pre>
83	while (insertVal < data[insertPos-1]) {
84	<pre>data[insertPos] = data[insertPos-1];</pre>
85	<pre>insertPos = insertPos-1;</pre>
86	}
87	data[insertPos] = insertVal;
88	}
89	/* Replace original lower-boundary element */
90	<pre>data[firstElement-1] = lowerBoundary;</pre>
91	}
92	This code is the same as Listing 31-1's. Although most people would agree that
93	the code's layout is much better than the first example's, the code is still not very
94	readable. The layout is still crowded and offers no clue to the routine's logical
95	organization. It's at about 0 on the number line of bad-to-good layout. The first
96	example was contrived, but the second one isn't at all uncommon. I've seen pro-
97	grams several thousand lines long with layout at least as bad as this; with no
98	documentation and bad variable names, overall readability was worse than in this
99	example. This code is formatted for the computer. There's no evidence that the
100	author expected the code to be read by humans. Listing 31-3 is an improvement.
101	Listing 31-3. Java layout example #3.
102	/* Use the insertion sort technique to sort the "data" array in ascending
103	order. This routine assumes that data[firstElement] is not the
104	first element in data and that data[firstElement-1] can be accessed.
105	*/
106	
107	<pre>public void InsertionSort(int[] data, int firstElement, int lastElement) {</pre>
108	// Replace element at lower boundary with an element guaranteed to be
109	// first in a sorted list.
110	<pre>int lowerBoundary = data[firstElement-1];</pre>
111	<pre>data[firstElement-1] = SORT_MIN;</pre>
112	
113	/* The elements in positions firstElement through sortBoundary-1 are

114	always sorted. In each pass through the loop, sortBoundary
115	is increased, and the element at the position of the
116	new sortBoundary probably isn't in its sorted place in the
117	array, so it's inserted into the proper place somewhere
118	between firstElement and sortBoundary.
119	*/
120	for (int sortBoundary = firstElement + 1; sortBoundary <= lastElement;
121	sortBoundary++) {
122	<pre>int insertVal = data[sortBoundary];</pre>
123	<pre>int insertPos = sortBoundary;</pre>
124	while (insertVal < data[insertPos - 1]) {
125	<pre>data[insertPos] = data[insertPos - 1];</pre>
126	<pre>insertPos = insertPos - 1;</pre>
127	}
128	<pre>data[insertPos] = insertVal;</pre>
129	}
130	
131	// Replace original lower-boundary element
132	<pre>data[firstElement - 1] = lowerBoundary;</pre>
133	}
134	This layout of the routine is a strong positive on the number line of bad-to-good
135	layout. The routine is now laid out according to principles that are explained
136	throughout this chapter. The routine has become much more readable, and the
137	effort that has been put into documentation and good variable names is now evi-
138	dent. The variable names were just as good in the earlier examples, but the lay-
139	out was so poor that they weren't helpful.
140 FURTHER READING For	The only difference between this example and the first two is the use of white
141 details on the typographic	space—the code and comments are exactly the same. White space is of use only
approach to formatting	to human readers—your computer could interpret any of the three fragments
source code, see Human Fac-	with equal ease. Don't feel bad if you can't do as well as your computer!
tors and Typography for	
More Readable Programs 144 (Baecker and Marcus 1990).	Still another formatting example is shown in Figure 31-1. It's based on a source-
145	code format developed by Ronald M. Baecker and Aaron Marcus (1990). In ad-
146	dition to using white space as the previous example did, it uses shading, different
147	typefaces, and other typographic techniques. Baecker and Marcus have devel-
	oped a tool that automatically prints normal source code in a way similar to that
148	
149	shown in Figure 31-1. Although the tool isn't commercially available, this sam-
150	ple is a glimpse of the source-code layout support that tools will offer within the
151	next few years.
152	The Fundamental Theorem of Formatting
153	The Fundamental Theorem of Formatting is that good visual layout shows the
154	logical structure of a program.
101	region structure of a program.

KEY POINT 156 157 158 159 160 161 162	Making the code look pretty is worth something, but it's worth less than showing the code's structure. If one technique shows the structure better and another looks better, use the one that shows the structure better. This chapter presents numerous examples of formatting styles that look good but misrepresent the code's logical organization. In practice, prioritizing logical representation usu- ally doesn't create ugly code—unless the logic of the code is ugly. Techniques that make good code look good and bad code look bad are more useful than techniques that make all code look good.
163 Any fool can write code	Human and Computer Interpretations of a Program
that a computer can un- derstand. Good pro- grammers write code that humans can understand. —Martin Fowler	Layout is a useful clue to the structure of a program. Whereas the computer might care exclusively about braces or <i>begin</i> and <i>end</i> , a human reader is apt to draw clues from the visual presentation of the code. Consider the code fragment in Listing 31-4, in which the indentation scheme makes it look to a human as if three statements are executed each time the loop is executed.
169	F31xx01
170	Figure 31-1.
171	Source-code formatting that exploits typographic features.
172 173	Listing 31-4. Java example of layout that tells different stories to hu- mans and computers.
174	// swap left and right elements for whole array
175	for (i = 0; i < MAX_ELEMENTS; i++)
176	<pre>leftElement = left[i];</pre>
177	<pre>left[i] = right[i];</pre>
178 179	<pre>right[i] = leftElement; If the code has no enclosing braces, the compiler will execute the first statement</pre>
180	MAX_ELEMENTS times and the second and third statements one time each. The
181	indentation makes it clear to you and me that the author of the code wanted all
182	three statements to be executed together and intended to put braces around them.
183	That won't be clear to the compiler.
184	Listing 31-5 is another example:
185	Listing 31-5. Another Java example of layout that tells different stories
186	to humans and computers.
187	x = 3+4 * 2+7;
188	A human reader of this code would be inclined to interpret the statement to mean
189	that x is assigned the value $(3+4) * (2+7)$, or 63. The computer will ignore the
190	white space and obey the rules of precedence, interpreting the expression as $3 + (42) = 7$
191	(4*2) + 7, or 18. The point is that a good layout scheme would make the visual

structure of a program match the logical structure, or tell the same story to the human that it tells to the computer.

How Much Is Good Layout Worth?

Our studies support the claim that knowledge of programming plans and rules of programming discourse can have a significant impact on program comprehension. In their book called [The] Elements of [Programming] Style, Kernighan and Plauger also identify what we would call discourse rules. Our empirical results put teeth into these rules: It is not merely a matter of aesthetics that programs should be written in a particular style. Rather there is a psychological basis for writing programs in a conventional manner: programmers have strong expectations that other programmers will follow these discourse rules. If the rules are violated, then the utility afforded by the expectations that programmers have built up over time is effectively nullified. The results from the experiments with novice and advanced student programmers and with professional programmers described in this paper provide clear support for these claims.

Elliot Soloway and Kate Ehrlich

In layout, perhaps more than in any other aspect of programming, the difference between communicating with the computer and communicating with human readers comes into play. The smaller part of the job of programming is writing a program so that the computer can read it; the larger part is writing it so that other humans can read it.

In their classic paper "Perception in Chess," Chase and Simon reported on a study that compared the abilities of experts and novices to remember the positions of pieces in chess (1973). When pieces were arranged on the board as they might be during a game, the experts' memories were far superior to the novices'. When the pieces were arranged randomly, there was little difference between the memories of the experts and the novices. The traditional interpretation of this result is that an expert's memory is not inherently better than a novice's but that the expert has a knowledge structure that helps him or her remember particular kinds of information. When new information corresponds to the knowledge structure-in this case, the sensible placement of chess pieces-the expert can remember it easily. When new information doesn't correspond to a knowledge structure-the chess pieces are randomly positioned-the expert can't remember it any better than the novice.

230	A few years later, Ben Shneiderman duplicated Chase and Simon's results in the
231	computer-programming arena and reported his results in a paper called "Explora-
232	tory Experiments in Programmer Behavior" (1976). Shneiderman found that
233	when program statements were arranged in a sensible order, experts were able to
234	remember them better than novices. When statements were shuffled, the experts'
235	superiority was reduced. Shneiderman's results have been confirmed in other
236	studies (McKeithen et al. 1981, Soloway and Ehrlich 1984). The basic concept
237	has also been confirmed in the games Go and bridge and in electronics, music,
238	and physics (McKeithen et al. 1981).
239	After I published the first edition of this book, Hank, one of the programmers
240	who reviewed the manuscript commented that, "I was surprised that you didn't
241	argue more strongly in favor of a brace style that looks like this:
242	for ()
243	{
244	
245	"I was surprised that you even included the brace style that looked like this:
246	for () {
247	}
248	"I thought that, with both Tony and me arguing for the first style, you'd prefer
249	that."
-	
250	I responded, "You mean you were arguing for the first style, and Tony was argu-
251	ing for the second style, don't you? Tony argued for the second style, not the
252	first."
253	Hank responded, "That's funny. The last project Tony and I worked on together,
254	I preferred style #2, and Tony preferred style #1. We spent the whole project
255	arguing about which style was best. I guess we talked one another into preferring
256	each other's styles!"
257 KEY POINT	This experience as well as the studies cited above suggest that structure helps
258	experts to perceive, comprehend, and remember important features of programs.
259	Given the variety of styles of layout and the tenacity with which programmers
260	cling to their own styles, even when they're vastly different from other styles,
261	it's easy to believe that the details of a specific method of structuring a program
262	are much less important than the fact that the program is structured at all.
263	Layout as Religion
204	The importance to comprehension and memory of star-staring and a
264	The importance to comprehension and memory of structuring one's environment
265	in a familiar way has led some researchers to hypothesize that layout might harm
266	an expert's ability to read a program if the layout is different from the scheme

268 269

270

271

272

273

274

275

276

the expert uses (Sheil 1981, Soloway and Ehrlich 1984). That possibility, compounded by the fact that layout is an aesthetic as well as a logical exercise, means that debates about program formatting often sound more like religious wars than philosophical discussions. At a coarse level, it's clear that some forms of layout are better than others. The

At a coarse level, it's clear that some forms of layout are better than others. The successively better layouts of the same code at the beginning of the chapter made that evident. This book won't steer clear of the finer points of layout just because they're controversial. Good programmers should be open-minded about their layout practices and accept practices proven to be better than the ones they're used to, even if adjusting to a new method results in some initial discomfort.

F31xx01

Figure 31-1

Source code formatting can be a religious topic to some developers. If you're mixing software and religion, you might read Section 34.9, "Thou Shalt Rend Software and Religion Asunder" before reading the rest of this chapter.

Objectives of Good Layout

Many decisions about layout details are a matter of subjective aesthetics—often, you can accomplish the same goal in many ways. You can make debates about subjective issues less subjective if you explicitly specify the criteria for your preferences. Explicitly, then, a good layout scheme should:

Accurately represent the logical structure of the code

That's the Fundamental Theorem of Formatting again—the primary purpose of good layout is to show the logical structure of the code. Typically, programmers use indentation and other white space to show the logical structure.

Consistently represent the logical structure of the code

Some styles of layout have rules with so many exceptions that it's hard to follow the rules consistently. A good style applies to most cases.

283

282

277

- ²⁸⁴ The results point out the
- ²⁸⁵ fragility of programming
- ²⁸⁶ expertise: advanced pro-
- ²⁸⁷ grammers have strong

32.5.

322 e researchers have explored

295	Improve readability
296	An indentation strategy that's logical but that makes the code harder to read is
297	useless. A layout scheme that calls for spaces only where they are required by
298	the compiler is logical but not readable. A good layout scheme makes code eas-
299	ier to read.
300	Withstand modifications
301	The best layout schemes hold up well under code modification. Modifying one
302	line of code shouldn't require modifying several others.
303	In addition to these criteria, minimizing the number of lines of code needed to
304	implement a simple statement or block is also sometimes considered.
305	How to Put the Layout Objectives to Use
306 KEY POINT	You can use the criteria for a good layout scheme to ground a discussion of lay-
307	out so that the subjective reasons for preferring one style over another are
308	brought into the open.
309	Weighting the criteria in different ways might lead to different conclusions. For
310	example, if you feel strongly that minimizing the number of lines used on the
311	screen is important—perhaps because you have a small computer screen—you
312	might criticize one style because it uses two more lines for a routine parameter
313	list than another.
314	31.2 Layout Techniques
315	You can achieve good layout by using a few layout tools in several different
316	ways. This section describes each of them.
317	White Space

Usewhitespacetoenhancereadability. White space, including spaces, tabs, line breaks, and blank lines, is the main tool available to you for showing a program's structure.

You wouldn't think of writing a book with no spaces between words, no paragraph breaks, and no divisions into chapters. Such a book might be readable cover to cover, but it would be virtually impossible to skim it for a line of thought or to find an important passage. Perhaps more important, the book's layout wouldn't show the reader how the author intended to organize the information. The author's organization is an important clue to the topic's logical organization.

328	Breaking a book into chapters, paragraphs, and sentences shows a reader how to
329	mentally organize a topic. If the organization isn't evident, the reader has to pro-
330	vide the organization, which puts a much greater burden on the reader and adds
331	the possibility that the reader may never figure out how the topic is organized.
332	The information contained in a program is denser than the information contained
333	in most books. Whereas you might read and understand a page of a book in a
334	minute or two, most programmers can't read and understand a naked program
335	listing at anything close to that rate. A program should give more organizational
336	clues than a book, not fewer.
337	Grouping
338	From the other side of the looking glass, white space is grouping, making sure
339	that related statements are grouped together.
340	In writing, thoughts are grouped into paragraphs. A well-written paragraph con-
341	tains only sentences that relate to a particular thought. It shouldn't contain extra-
342	neous sentences. Similarly, a paragraph of code should contain statements that
343	accomplish a single task and that are related to each other.
344	Blank lines
345	Just as it's important to group related statements, it's important to separate unre-
346	lated statements from each other. The start of a new paragraph in English is iden-
347	tified with indentation or a blank line. The start of a new paragraph of code
348	should be identified with a blank line.
349	Using blank lines is a way to indicate how a program is organized. You can use
350	them to divide groups of related statements into paragraphs, to separate routines
351	from one another, and to highlight comments.
352 HARD DATA	Although this particular statistic may be hard to put to work, a study by Gorla,
353	Benander, and Benander found that the optimal number of blank lines in a pro-
354	gram is about 8 to 16 percent. Above 16 percent, debug time increases dramati-
355	cally (1990).
356	Indentation
357	Use indentation to show the logical structure of a program. As a rule, you should
358	indent statements under the statement to which they are logically subordinate.
359 HARD DATA	Indentation has been shown to be correlated with increased programmer com-
360	prehension. The article "Program Indentation and Comprehensibility" reported
361	that several studies found correlations between indentation and improved com-
362	prehension (Miaria et al. 1983). Subjects scored 20 to 30 percent higher on a test
363	of comprehension when programs had a two-to-four-spaces indentation scheme
364	than they did when programs had no indentation at all.

365 HARD DATA 366 367 368 369 370 371	The same study found that it was important to neither under-emphasize nor over- emphasize a program's logical structure. The lowest comprehension scores were achieved on programs that were not indented at all. The second lowest were achieved on programs that used six-space indentation. The study concluded that two-to-four-space indentation was optimal. Interestingly, many subjects in the experiment felt that the six-space indentation was easier to use than the smaller indentations, even though their scores were lower. That's probably because six-
372 373 374	space indentation looks pleasing. But regardless of how pretty it looks, six-space indentation turns out to be less readable. This is an example of a collision be- tween aesthetic appeal and readability.
375	Parentheses
376 377 378 379	Use more parentheses than you think you need. Use parentheses to clarify expressions that involve more than two terms. They may not be needed, but they add clarity and they don't cost you anything. For example, how are the following expressions evaluated?
380	C++ Version: 12 + 4 % 3 * 7 / 8
381	Visual Basic Version: $12 + 4 \mod 3 \times 7 \setminus 8$
382 383 384 385 386	The key question is, did you have to think about how the expressions are evalu- ated? Can you be confident in your answer without checking some references? Even experienced programmers don't answer confidently, and that's why you should use parentheses whenever there is any doubt about how an expression is evaluated.
387	31.3 Layout Styles
388 389 390 391 392 393 394	Most layout issues have to do with laying out blocks, the groups of statements below control statements. A block is enclosed between braces or keywords: <i>{</i> and <i>}</i> in C++ and Java; <i>if-then-endif</i> in Visual Basic; and other similar structures in other languages. For simplicity, much of this discussion uses <i>begin</i> and <i>end</i> generically, assuming that you can figure out how the discussion applies to braces in C++ and Java or other blocking mechanisms in other languages. The following sections describe four general styles of layout:
395	• Pure blocks
396	• Emulating pure blocks
397	 using <i>begin-end</i> pairs (braces) to designate block boundaries Endline layout
398	• Endline layout

399	Pure Blocks
400	Much of the layout controversy stems from the inherent awkwardness of the
401	more popular programming languages. A well-designed language has clear block
402	structures that lend themselves to a natural indentation style. In Visual Basic, for
403	example, each control construct has its own terminator, and you can't use a con-
404	trol construct without using the terminator. Code is blocked naturally. Some ex-
405	amples in Visual Basic are shown in Listing 31-6, Listing 31-7, and Listing 31-8:
406	Listing 31-6. Visual Basic example of a pure <i>if</i> block.
407	If pixelColor = Color_Red Then
408	statement1
409	statement2
410	
411	End If

428	Case Else
420	statement1
430	statement2
431	
432	End Select
433	A control construct in Visual Basic always has a beginning statement—If-Then,
434	<i>While</i> , and <i>Select-Case</i> in the examples—and it always has a corresponding <i>End</i>
435	statement. Indenting the inside of the structure isn't a controversial practice, and
436	the options for aligning the other keywords are somewhat limited. Listing 31-9 is
437	an abstract representation of how this kind of formatting works:
438	Listing 31-9. Abstract example of the pure-block layout style.
439	
440	B

С

D

In this example, statement A begins the control construct and statement D ends the control construct. The alignment between the two provides solid visual closure.

The controversy about formatting control structures arises in part from the fact that some languages don't *require* block structures. You can have an *if-then* followed by a single statement and not have a formal block. You have to add a *begin-end* pair or opening and closing braces to create a block rather than getting one automatically with each control construct. Uncoupling *begin* and *end* from the control structure—as languages like C++ and Java do with { and }—leads to questions about where to put the *begin* and *end*. Consequently, many indentation problems are problems only because you have to compensate for poorly designed language structures. Various ways to compensate are described in the following sections.

Emulating Pure Blocks

A good approach in languages that don't have pure blocks is to view the *begin* and *end* keywords (or *[* and *]* tokens) as extensions of the control construct they're used with. Then it's sensible to try to emulate the Visual Basic formatting in your language. Listing 31-10is an abstract view of the visual structure you're trying to emulate:

Listing 31-10. Abstract example of the pure-block layout style.

In this style, the control structure opens the block in statement A and finishes the block in statement D. This implies that the *begin* should be at the end of statement A and the *end* should be statement D. In the abstract, to emulate pure blocks, you'd have to do something like Listing 31-11:

Listing 31-11. Abstract example of emulating the pure-block style.

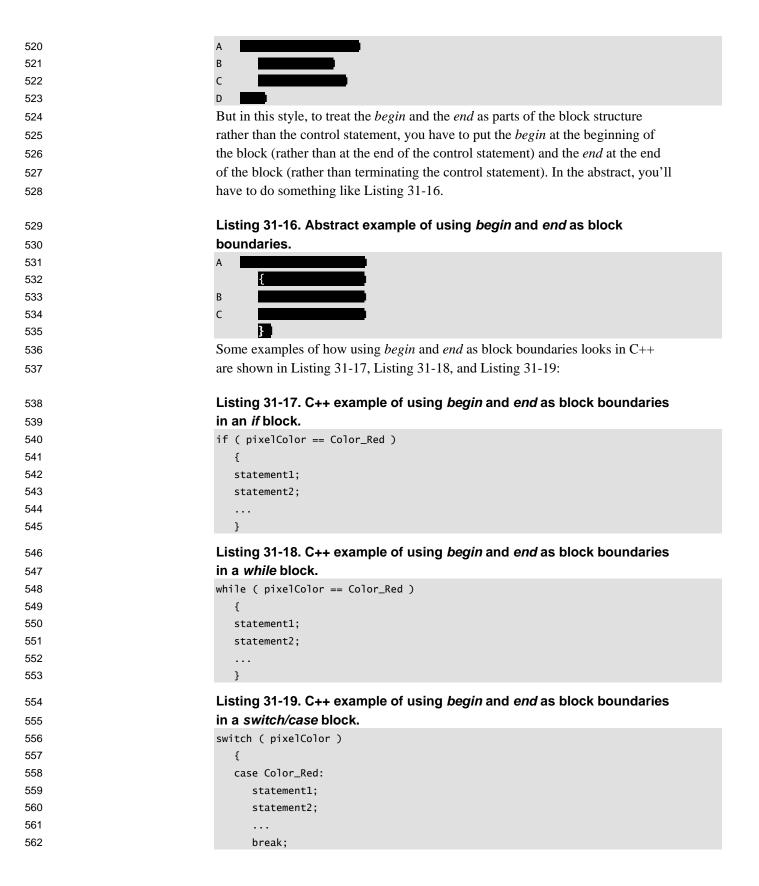

Some examples of how the style looks in C++ are shown in Listing 31-12, Listing 31-13, and Listing 31-14:

Listing 31-12. C++ example of emulating a pure *if* block.

if (pixelColor == Color_Red) {

```
480
                                    statement1:
481
                                    statement2;
482
                                    . . .
483
                                 }
                                 Listing 31-13. C++ example of emulating a pure while block.
484
                                 while ( pixelColor == Color_Red ) {
485
486
                                    statement1;
487
                                    statement2;
488
                                    . . .
489
                                 }
                                 Listing 31-14. C++ example of emulating a pure switch/case block.
490
                                 switch ( pixelColor ) {
491
                                    case Color_Red:
492
493
                                       statement1;
494
                                       statement2;
495
                                       . . .
496
                                    break:
497
                                    case Color_Green:
498
                                       statement1;
499
                                       statement2;
500
                                       . . .
501
                                    break;
502
                                    default:
503
                                       statement1;
504
                                       statement2;
505
                                       . . .
506
                                    break;
507
                                 }
                                 This style of alignment works pretty well. It looks good, you can apply it consis-
508
509
                                 tently, and it's maintainable. It supports the Fundamental Theorem of Formatting
                                 in that it helps to show the logical structure of the code. It's a reasonable style
510
                                 choice. This style is standard in Java and common in C++.
511
                                 Using begin-end pairs (braces) to Designate Block
512
                                 Boundaries
513
                                 A substitute for a pure block structure is to view begin-end pairs as block
514
                                 boundaries. If you take that approach, you view the begin and the end as state-
515
                                 ments that follow the control construct rather than as fragments that are part of it.
516
517
                                 Graphically, this is the ideal, just as it was with the pure-block emulation shown
                                 again in Listing 31-15:
518
                                 Listing 31-15. Abstract example of the pure-block layout style.
519
```

case Color_Green:
statement1;
statement2;
break;
default:
statement1;
statement2;
break;

This alignment style works well. It supports the Fundamental Theorem of Formatting by exposing the code's underlying logical structure. Its only limitation is that it can't be applied literally in *switch/case* statements in C++ and Java, as shown by Listing 31-19. (The *break* keyword is a substitute for the closing brace, but there is no equivalent to the opening brace.)

Endline Layout

Another layout strategy is "endline layout," which refers to a large group of layout strategies in which the code is indented to the middle or end of the line. The endline indentation is used to align a block with the keyword that began it, to make a routine's subsequent parameters line up under its first parameter, to line up cases in a *case* statement, and for other similar purposes. Listing 31-20 is an abstract example:

In this example, statement A begins the control construct and statement D ends it. Statements B, C, and D are aligned under the keyword that began the block in statement A. The uniform indentation of B, C, and D shows that they're grouped together. Listing 31-21 is a less abstract example of code formatted using this strategy:

Listing 31-21. Visual Basic example of endline layout of a while block.

```
While ( pixelColor = Color_Red )
    statement1;
    statement2;
    ...
    Wend
```

602		In the example, the <i>begin</i> is placed at the end of the line rather than under the
603		corresponding keyword. Some people prefer to put <i>begin</i> under the keyword, but
604		choosing between those two fine points is the least of this style's problems.
605		The endline layout style works acceptably in a few cases. Listing 31-22 is an
606		example in which it works:
000		example in which it works.
607		Listing 31-22. A rare Visual Basic example in which endline layout
608		seems appealing.
609		If (soldCount > 1000) Then
610		markdown = 0.10
611		profit = 0.05
612	The else keyword is aligned	Else
613	with the then keyword above	markdown = 0.05
614	it.	End If
615	<i>.</i>	In this case, the <i>Then</i> , <i>Else</i> , and <i>End If</i> keywords are aligned, and the code fol-
616		lowing them is also aligned. The visual effect is a clear logical structure.
617		If you look critically at the earlier <i>case</i> -statement example, you can probably
617		
618		predict the unraveling of this style. As the conditional expression becomes more
619		complicated, the style will give useless or misleading clues about the logical
620		structure. Listing 31-23 is an example of how the style breaks down when it's
621		used with a more complicated conditional:
021		
021

poses a maintenance problem that pure block, pure-block emulation, and using begin-end to designate block boundaries do not.

You might think that these examples are contrived just to make a point, but this style has been persistent despite its drawbacks. Numerous textbooks and programming references have recommended this style. The earliest book I saw that recommended this style was published in the mid-1970s and the most recent was published in 2003.

Overall, endline layout is inaccurate, hard to apply consistently, and hard to maintain. You'll see other problems with endline layout throughout the chapter.

Which Style Is Best?

If you're working in Visual Basic, use pure-block indentation. (The Visual Basic IDE makes it hard not to use this style anyway.)

In Java, standard practice is to use pure-block indentation.

In C++, you might simply choose the style you like or the one that is preferred by the majority of people on your team. Either pure-block emulation or *beginend* block boundaries work equally well. The only study that has compared the two styles found no statistically significant difference between the two as far as understandability is concerned (Hansen and Yim 1987).

Neither of the styles is foolproof, and each requires an occasional "reasonable and obvious" compromise. You might prefer one or the other for aesthetic reasons. This book uses pure block style in its code examples, so you can see many more illustrations of how that style works just by skimming through the examples. Once you've chosen a style, you reap the most benefit from good layout when you apply it consistently.

31.4 Laying Out Control Structures

The layout of some program elements is primarily a matter of aesthetics. Layout of control structures, however, affects readability and comprehensibility and is therefore a practical priority.

Fine Points of Formatting Control-Structure Blocks

Working with control-structure blocks requires attention to some fine details. Here are some guidelines:

674		Avoid unindented begin-end pairs
675		In the style shown in Listing 31-24, the begin-end pair is aligned with the control
676		structure, and the statements that begin and end enclose are indented under be-
677		gin.
678		Listing 31-24. Java example of unindented <i>begin-end</i> pairs.
679	The begin is aligned with the	<pre>for (int i = 0; i < MAX_LINES; i++) </pre>
680	for.	
681	The statements are indented	ReadLine(i);
682 683	<i>under</i> begin.	<pre>ProcessLine(i); }</pre>
684	The end is aligned with the for.	Although this approach looks fine, it violates the Fundamental Theorem of For-
685		matting; it doesn't show the logical structure of the code. Used this way, the
686		<i>begin</i> and <i>end</i> aren't part of the control construct, but they aren't part of the
687		statement(s) after it either.
007		statement(s) after it entier.
688		Listing 31-25 is an abstract view of this approach:
689		Listing 31-25. Abstract example of misleading indentation.
690		
691		B Harden
692		C
693		D
694		
695		In this example, is statement B subordinate to statement A? It doesn't look like
696		part of statement A, and it doesn't look as if it's subordinate to it either. If you
697		have used this approach, change to one of the two layout styles described earlier,
698		and your formatting will be more consistent.
699		Avoid double indentation with begin and end
700		A corollary to the rule against nonindented <i>begin-end</i> pairs is the rule against
701		doubly indented <i>begin-end</i> pairs. In this style, shown in Listing 31-26, <i>begin</i> and
702		<i>end</i> are indented and the statements they enclose are indented again:
703		Listing 31-26. Java example of inappropriate double indentation of
704		begin-end block.
705	CODING HORROR	for (int i = 0; i < MAX_LINES; i++)
706		{
707	The statements below the	ReadLine(i);
708	begin are indented as if they	<pre>ProcessLine(i);</pre>
709	were subordinate to it.	}
710		This is another example of a style that looks fine but violates the Fundamental
711		Theorem of Formatting. One study showed no difference in comprehension be-
712		tween programs that are singly indented and programs that are doubly indented
713		(Miaria et al. 1983), but this style doesn't accurately show the logical structure

of the program; *ReadLine()* and *ProcessLine()* are shown as if they are logically subordinate to the *begin-end* pair, and they aren't.

The approach also exaggerates the complexity of a program's logical structure. Which of the structures shown in Listing 31-27 and Listing 31-28 looks more complicated?

Listing 31-27. Abstract Structure 1.

Listing 31-28. Abstract Structure 2.

Other Considerations

Although indentation of blocks is the major issue in formatting control structures, you'll run into a few other kinds of issues. Here are some more guidelines:

Use blank lines between paragraphs

Some blocks of code aren't demarcated with *begin-end* pairs. A logical block—a group of statements that belong together—should be treated the way paragraphs in English are. Separate them from each other with blank lines. Listing 31-29 shows an example of paragraphs that should be separated.

Listing 31-29. C++ example of code that should be grouped and separated.

748	cursor.start = startingScanLine;
749	<pre>cursor.end = endingScanLine;</pre>

795		one-statement;
796		}
797		
798	Style 2b	if (expression)
799		{
800		one-statement;
801		}
802		
803	Style 3	if (expression) one-statement;
804		There are arguments in favor of each of these approaches. Style 1 follows the
805		indentation scheme used with blocks, so it's consistent with other approaches.
806		Style 2 (either 2a or 2b) is also consistent, and the <i>begin-end</i> pair reduces the
807		chance that you'll add statements after the <i>if</i> test and forget to add <i>begin</i> and <i>end</i> .
808		This would be a particularly subtle error because the indentation would tell you
809		that everything is OK, but the indentation wouldn't be interpreted the same way
810		by the compiler. Style 3's main advantage over Style 2 is that it's easier to type.
811		Its advantage over Style 1 is that if it's copied to another place in the program,
812		it's more likely to be copied correctly. Its disadvantage is that in a line-oriented
813		debugger, the debugger treats the line as one line and the debugger doesn't show
814		you whether it executes the statement after the <i>if</i> test.
815		I've used Style 1 and have been the victim of incorrect modification many times.
816		I don't like the exception to the indentation strategy caused by Style 3, so I avoid
817		it altogether. On a group project, I favor either variation of Style 2 for its consis-
818		tency and safe modifiability. Regardless of the style you choose, use it consis-
819		tently and use the same style for <i>if</i> tests and all loops.
820		For complicated expressions, put separate conditions on separate lines
821		Put each part of a complicated expression on its own line. Listing 31-32 shows
822		an expression that's formatted without any attention to readability:
823		Listing 31-32. Java example of an essentially unformatted (and unread-
824		able) complicated expression.
825		if ((('0' <= inChar) && (inChar <= '9')) (('a' <= inChar) &&
826		(inChar <= 'z')) (('A' <= inChar) && (inChar <= 'Z')))
827		
828		This is an example of formatting for the computer instead of for human readers.
829		By breaking the expression into several lines, as in Listing 31-33, you can im-
830		prove readability.
831		Listing 31-33. Java example of a readable complicated expression.

832 CROSS-REFERENCE An-833 other technique for making 834 complicated expressions readable is to put them into 835 boolean functions. For details 836 on putting complicated ex-837 pressions into boolean func-838 tions and other readability techniques, see Section 19.1, 839 "Boolean Expressions." 840 841 Avoid gotos 842 CROSS-REFERENCE For 843 details on the use of gotos, see in Section 17.3, "goto." 844 845 846 847 848 849 850 Goto labels should be 851 left-aligned in all caps 852 and should include the programmer's name, 853 home phone number, and 854 credit card number. 855 -Abdul Nizar 856 857 858 **CROSS-REFERENCE** For 859 other methods of addressing 860 goto). this problem, see "Error 861 Processing and gotos" in 862 Section 17.3. 863 864 865 866 867 868 869 870 871

```
if ( ( ( '0' <= inChar ) && ( inChar <= '9' ) ) ||
   (('a' <= inChar) && (inChar <= 'z')) ||
   ( ( 'A' <= inChar ) && ( inChar <= 'Z' ) ) )
```

The second fragment uses several formatting techniques-indentation, spacing, number-line ordering, and making each incomplete line obvious-and the result is a readable expression. Moreover, the intent of the test is clear. If the expression contained a minor error, such as using a z instead of a Z, it would be obvious in code formatted this way, whereas the error wouldn't be clear with less careful formatting.

The original reason to avoid gotos was that they made it difficult to prove that a program was correct. That's a nice argument for all the people who want to prove their programs correct, which is practically no one. The more pressing problem for most programmers is that *gotos* make code hard to format. Do you indent all the code between the goto and the label it goes to? What if you have several gotos to the same label? Do you indent each new one under the previous one? Here's some advice for formatting gotos:

- Avoid gotos. This sidesteps the formatting problem altogether.
- Use a name in all caps for the label the code goes to. This makes the label obvious.
- Put the statement containing the goto on a line by itself. This makes the goto obvious.
- Put the label the goto goes to on a line by itself. Surround it with blank lines. This makes the label obvious. Outdent the line containing the label to the left margin to make the label as obvious as possible.

Listing 31-34 shows these goto layout conventions at work.

Listing 31-34. C++ example of making the best of a bad situation (using

```
void PurgeFiles( ErrorCode & errorCode ) {
   FileList fileList;
   int numFilesToPurge = 0;
   MakePurgeFileList( fileList, numFilesToPurge );
   errorCode = FileError_Success;
   int fileIndex = 0:
   while ( fileIndex < numFilesToPurge ) {</pre>
      DataFile fileToPurge;
      if ( !FindFile( fileList[ fileIndex ], fileToPurge ) ) {
         errorCode = FileError_NotFound;

967 CROSS-REFERENCE For

968 "Commenting Individual Lines" in Section 32.5.

details on documenting individual statements, see

961	If you have a <i>case</i> statement in which all the cases are exactly parallel and all the
962	actions are short, you could consider putting the case and action on the same
963	line. In most instances, however, you'll live to regret it. The formatting is a pain
964	initially and breaks under modification, and it's hard to keep the structure of all
965	the cases parallel as some of the short actions become longer ones.

31.5 Laying Out Individual Statements

This section explains many ways to improve individual statements in a program.

Statement Length

A common rule is to limit statement line length to 80 characters. Here are the reasons:

- Lines longer than 80 characters are hard to read. .
- The 80-character limitation discourages deep nesting. .
- Lines longer than 80 characters often won't fit on 8.5" x 11" paper. •
- Paper larger than 8.5" x 11" is hard to file. •

With larger screens, narrow typefaces, laser printers, and landscape mode, the arguments for the 80-character limit aren't as compelling as they used to be. A single 90-character-long line is usually more readable than one that has been broken in two just to avoid spilling over the 80th column. With modern technology, it's probably all right to exceed 80 columns occasionally.

Using Spaces for Clarity

Add white space within a statement for the sake of readability:

Use spaces to make logical expressions readable

The expression

while(pathName[startPath+position]<>';') and ((startPath+position)<length(pathName)) do</pre> is about as readable as Idareyoutoreadthis.

As a rule, you should separate identifiers from other identifiers with spaces. If you use this rule, the while expression looks like this:

while (pathName[startPath+position] <> ';') and ((startPath + position) < length(pathName)) do

991	Some software artists might recommend enhancing this particular expression
992	with additional spaces to emphasize its logical structure, this way:
993	while (pathName[startPath + position] <> ';') and
994	((startPath + position) < length(pathName)) do
995	This is fine, although the first use of spaces was sufficient to ensure readability.
996	Extra spaces hardly ever hurt, however, so be generous with them.
997	Use spaces to make array references readable
998	The expression
999	grossRate[census[groupId].gender,census[groupId].ageGroup]
1000	is no more readable than the earlier dense while expression. Use spaces around
1001	each index in the array to make the indexes readable. If you use this rule, the
1002	expression looks like this:
1003	grossRate[census[groupId].gender, census[groupId].ageGroup]
1004	Use spaces to make routine arguments readable
1005	What is the fourth argument to the following routine?
1006	ReadEmployeeData(maxEmps,empData,inputFile,empCount,inputError);
1007	Now, what is the fourth argument to the following routine?
1008	GetCensus(inputFile, empCount, empData, maxEmps, inputError);
1009	Which one was easier to find? This is a realistic, worthwhile question because
1010	argument positions are significant in all major procedural languages. It's com-
1011	mon to have a routine specification on one half of your screen and the call to the
1012	routine on the other half, and to compare each formal parameter with each actual
1013	parameter.
1014	Formatting Continuation Lines
1015	One of the most vexing problems of program layout is deciding what to do with
1016	the part of a statement that spills over to the next line. Do you indent it by the
1017	normal indentation amount? Do you align it under the keyword? What about
1018	assignments?
1019	Here's a sensible, consistent approach that's particularly useful in Java, C, C++,
1020	Visual Basic, and other languages that encourage long variable names.
1021	Make the incompleteness of a statement obvi
1022	ous
1023	Sometimes a statement must be broken across lines, either because it's longer
1024	than programming standards allow or because it's too absurdly long to put on
1025	one line. Make it obvious that the part of the statement on the first line is only

1026		part of a statement. The easiest way to do that is to break up the statement so that
1027		the part on the first line is blatantly incorrect syntactically if it stands alone.
1028		Some examples are shown in Listing 31-37:
1029		Listing 31-37. Java examples of obviously incomplete statements.
1030	The && signals that the	<pre>while (pathName[startPath + position] != ';') &&</pre>
1031	statement isn't complete.	((startPath + position) <= pathName.length())
1032		•••
1033		
1034	The plus sign (+) signals that	<pre>totalBill = totalBill + customerPurchases[customerID] +</pre>
1035	the statement isn't complete.	<pre>SalesTax(customerPurchases[customerID]);</pre>
1036		
1037		
1038	The comma (,) signals that	DrawLine(window.north, window.south, window.east, window.west,
1039	the statement isn't complete.	currentWidth, currentAttribute);
1040		
1041		In addition to telling the reader that the statement isn't complete on the first line,
1042		the break helps prevent incorrect modifications. If the continuation of the state-
1043		ment were deleted, the first line wouldn't look as if you had merely forgotten a
1044		parenthesis or semicolon-it would clearly need something more.
1015		Keep closely related elements together
1045		
1046		When you break a line, keep things together that belong together—array refer-
1047		ences, arguments to a routine, and so on. The example shown in Listing 31-38is
1048		poor form:
1049		Listing 31-38. Java example of breaking a line poorly.
	CODING HORROR	<pre>customerBill = PreviousBalance(paymentHistory[customerID]) + LateCharge(</pre>
1051		<pre>paymentHistory[customerID]);</pre>
1052		Admittedly, this line break follows the guideline of making the incompleteness
1053		of the statement obvious, but it does so in a way that makes the statement unnec-
1054		essarily hard to read. You might find a case in which the break is necessary, but
1055		in this case it isn't. It's better to keep the array references all on one line. Listing
1056		31-39 shows better formatting:
1057		Listing 31-39. Java example of breaking a line well.
1058		<pre>customerBill = PreviousBalance(paymentHistory[customerID]) +</pre>
1059		LateCharge(paymentHistory[customerID]);
1000		In Jack months and a section where the section days and and and
1060		Indent routine-call continuation lines the standard amount
1061		If you normally indent three spaces for statements in a loop or a conditional, in-
1062		dent the continuation lines for a routine by three spaces. Some examples are
1063		shown in Listing 31-40:

1064 1065	Listing 31-40. Java examples of indenting routine-call continuation lines using the standard indentation increment.
1066	DrawLine(window.north, window.south, window.east, window.west,
1067	currentWidth, currentAttribute);
1068	<pre>SetFontAttributes(faceName[fontId], size[fontId], bold[fontId],</pre>
1069	<pre>italic[fontId], syntheticAttribute[fontId].underline,</pre>
1070	<pre>syntheticAttribute[fontId].strikeout);</pre>
1071	One alternative to this approach is to line up the continuation lines under the first
1072	argument to the routine, as shown in Listing 31-41:
1073	Listing 31-41. Java examples of indenting a routine-call continuation
1074	line to emphasize routine names.
1075	DrawLine(window.north, window.south, window.east, window.west,
1076	<pre>currentWidth, currentAttribute);</pre>
1077	<pre>SetFontAttributes(faceName[fontId], size[fontId], bold[fontId],</pre>
1078	<pre>italic[fontId], syntheticAttribute[fontId].underline,</pre>
1079	<pre>syntheticAttribute[fontId].strikeout);</pre>
1080	From an aesthetic point of view, this looks a little ragged compared to the first
1081	approach. It is also difficult to maintain as routine names changes, argument
1082	names change, and so on. Most programmers tend to gravitate toward the first
1083	style over time.
1084	Make it easy to find the end of a continuation line
1085	One problem with the approach shown above is that you can't easily find the end
1086	of each line. Another alternative is to put each argument on a line of its own and
1087	indicate the end of the group with a closing parenthesis. Listing 31-42 shows
1088	how it looks.
1089	Listing 31-42. Java examples of formatting routine-call continuation
1090	lines one argument to a line.
1091	DrawLine(
1092	window.north,
1093	window.south,
1094	window.east,
1095	window.west,
1096	currentWidth,
1097	currentAttribute
1098);
1099	
1100	SetFontAttributes(
1101	<pre>faceName[fontId],</pre>
1102	size[fontId],
1103	bold[fontId],
1104	italic[fontId],
1105	<pre>syntheticAttribute[fontId].underline, syntheticAttribute[fontId] strikeout</pre>
1106	syntheticAttribute[fontId].strikeout

1107);
1108	This approach takes up a lot of real estate. If the arguments to a routine are long
1109	object-field references or pointer names, however, as the last two are, using one
1110	argument per line improves readability substantially. The); at the end of the
1111	block makes the end of the call clear. You also don't have to reform t when you
1112	add a parameter; you just add a new line.
1112	add a parameter, you just add a new mie.
1113	In practice, usually only a few routines need to be broken into multiple lines.
1114	You can handle others on one line. Any of the three options for formatting mul-
1115	tiple-line routine calls works all right if you use it consistently.
1110	upie fine founde cuits works un right if you use it consistently.
1116	Indent control-statement continuation lines the standard amount
1117	If you run out of room for a for loop, a while loop, or an if statement, indent the
1118	continuation line by the same amount of space that you indent statements in a
1119	loop or after an <i>if</i> statement. Two examples are shown in Listing 31-43:
1120	Listing 31-43. Java examples of indenting control-statement continua-
1121	tion lines.
1122	<pre>while ((pathName[startPath + position] != ';') &&</pre>
1123 This continuation line is	<pre>((startPath + position) <= pathName.length())) {</pre>
1124 indented the standard number	
1125 of spaces	}
1126	
1127	<pre>for (int employeeNum = employee.first + employee.offset;</pre>
1128as is this one.	<pre>employeeNum < employee.first + employee.offset + employee.total;</pre>
1129	<pre>employeeNum++) {</pre>
1130	
1131	}
1132 CROSS-REFERENCE Som	This meets the criteria set earlier in the chapter. The continuation part of the
1133 etimes the best solution to a	statement is done logically—it's always indented underneath the statement it
complicated test is to put it	continues. The indentation can be done consistently—it uses only a few more
into a boolean function. For	spaces than the original line. It's as readable as anything else, and it's as main-
examples, see waking	tainable as anything else. In some cases you might be able to improve readability
1136 Complicated Expressions1137 Simple" in Section 19.1.	by fine-tuning the indentation or spacing, but be sure to keep the maintainability
1137 Shiple in Section 19.1.	trade-off in mind when you consider fine-tuning.
1130	trade-on in mind when you consider mie-tuning.
1139	Do not align right sides of assignment statements
1140	In the first edition of this book I recommended aligning the right sides of state-
1141	ments containing assignments as shown in Listing 31-44:
1142	Listing 31-44. Java example of endline layout used for assignment-
1143	statement continuation—bad practice.
1144	<pre>customerPurchases = customerPurchases + CustomerSales(CustomerID);</pre>
1144 1145	<pre>customerPurchases = customerPurchases + CustomerSales(CustomerID); customerBill = customerBill + customerPurchases;</pre>

1147	<pre>LateCharge(customerID);</pre>
1148	<pre>customerRating = Rating(customerID, totalCustomerBill);</pre>
1149	With the benefit of 10 years' hindsight, I have found that while this indentation
1150	style might look attractive it becomes a headache to maintain the alignment of
1151	the equals signs as variable names change, code is run through tools that substi-
1152	tute tabs for spaces and spaces for tabs. It is also hard to maintain as lines are
1153	moved among different parts of the program that have different levels of indenta-
1154	tion.
1155	For consistency with the other indentation guidelines as well as maintainability,
1156	treat groups of statements containing assignment operations just as you would
1157	treat other statements, as Listing 31-45 shows:
1158	Listing 31-45. Java example of standard indentation for assignment-
1159	statement continuation—good practice.
1160	<pre>customerPurchases = customerPurchases + CustomerSales(CustomerID);</pre>
1161	<pre>customerBill = customerBill + customerPurchases;</pre>
1162	<pre>totalCustomerBill = customerBill + PreviousBalance(customerID) +</pre>
1163	LateCharge(customerID);
1164	<pre>customerRating = Rating(customerID, totalCustomerBill);</pre>
1165	Indent assignment-statement continuation lines the standard amount
1166	In Listing 31-45, the continuation line for the third assignment statement is in-
1167	dented the standard amount. This is done for the same reasons that assignment
1168	statements in general are not formatted in any special way-general readability
1169	and maintainability.
1170	Using Only One Statement per Line
1171	Modern languages such as C++ and Java allow multiple statements per line. The
1172	power of free formatting is a mixed blessing, however, when it comes to putting
1173	multiple statements on a line:
1174	i = 0; j = 0; k = 0; DestroyBadLoopNames(i, j, k);
1175	This line contains several statements that could logically be separated onto lines
1176	of their own.
1177	One argument in favor of putting several statements on one line is that it requires
1178	fewer lines of screen space or printer paper, which allows more of the code to be
1179	viewed at once. It's also a way to group related statements, and some program-
1180	mers believe that it provides optimization clues to the compiler.
1181	These are good reasons, but the reasons to limit yourself to one statement per
1182	line are more compelling:

1183 1184 1185 1186	• Putting each statement on a line of its own provides an accurate view of a program's complexity. It doesn't hide complexity by making complex statements look trivial. Statements that are complex look complex. Statements that are easy look easy.
1187CROSS-REFERENCECod1188e-level performance optimi- zations are discussed in Chapter 25, "Code-Tuning	• Putting several statements on one line doesn't provide optimization clues to modern compilers. Today's optimizing compilers don't depend on format- ting clues to do their optimizations. This is illustrated later in this section.
 1190 Strategies," and Chapter 26, 1191 "Code-Tuning Techniques." 1192 1193 1194 	• With statements on their own lines, the code reads from top to bottom, in- stead of top to bottom and left to right. When you're looking for a specific line of code, your eye should be able to follow the left margin of the code. It shouldn't have to dip into each and every line just because a single line might contain two statements.
1195 1196 1197 1198	• With statements on their own lines, it's easy to find syntax errors when your compiler provides only the line numbers of the errors. If you have multiple statements on a line, the line number doesn't tell you which statement is in error.
1199 1200 1201 1202	• With one statement to a line, it's easy to step through the code with line- oriented debuggers. If you have several statements on a line, the debugger executes them all at once, and you have to switch to assembler to step through individual statements.
1203 1204 1205	• With one to a line, it's easy to edit individual statements—to delete a line or temporarily convert a line to a comment. If you have multiple statements on a line, you have to do your editing between other statements.
1206	In C++, avoid using multiple operations per line (side effects)
1207	Side effects are consequences of a statement other than its main consequence. In
1208	C++, the $++$ operator on a line that contains other operations is a side effect.
1209	Likewise, assigning a value to a variable and using the left side of the assign-
1210	ment in a conditional is a side effect.
1211	Side effects tend to make code difficult to read. For example, if <i>n</i> equals 4, what
1212	is the printout of the statement shown in Listing 31-46?
1213	Listing 31-46. C++ example of an unpredictable side effect.
1214	<pre>PrintMessage(++n, n + 2);</pre>
1215	Is it 4 and 6? Is it 5 and 7? Is it 5 and 6? The answer is None of the above. The
1216	first argument, $++n$, is 5. But the C++ language does not define the order in
1217	which terms in an expression or arguments to a routine are evaluated. So the
1218	compiler can evaluate the second argument, $n + 2$, either before or after the first
1219	argument; the result might be either 6 or 7 , depending on the compiler. Listing
1220	31-47 shows how you should rewrite the statement so that the intent is clear:

1221	Listing 31-47. C++ example of avoiding an unpredictable side effect.
1222	++n;
1223	PrintMessage(n, n + 2);
1224	If you're still not convinced that you should put side effects on lines by them-
1225	selves, try to figure out what the routine shown in Listing 31-48 does:
1226	Listing 31-48. C example of too many operations on a line.
1227	<pre>strcpy(char * t, char * s) {</pre>
1228	while (*++t = *++s)
1229	;
1230	}
1231	Some experienced C programmers don't see the complexity in that example be-
1232	cause it's a familiar function; they look at it and say, "That's <i>strcpy()</i> ." In this
1233	case, however, it's not quite <i>strcpy()</i> . It contains an error. If you said, "That's
1234	<i>strcpy()</i> " when you saw the code, you were recognizing the code, not reading it.
1235	This is exactly the situation you're in when you debug a program: The code that
1236	you overlook because you "recognize" it rather than read it can contain the error
1237	that's harder to find than it needs to be.
1238	The fragment shown in Listing 31-49 is functionally identical to the first and is
1239	more readable:
1240	Listing 31-49. C example of a readable number of operations on each
1210	Listing 51-45. O example of a readable number of operations on each
1241	line.
1241	line.

1261

1262

1263

1296

1264	Even if you read statements with side effects easily, take pity on other people
1265	who will read your code. Most good programmers need to think twice to under-
1266	stand expressions with side effects. Let them use their brain cells to understand
1267	the larger questions of how your code works rather than the syntactic details of a
1268	specific expression.
1269	Laying Out Data Declarations
CROSS-REFERENCEFor details on documenting data1271declarations, see "Comment-	<i>Use only one data declaration per line</i> As shown in the examples above, you should give each data declaration its own
1272 ing Data Declarations" in	line. It's easier to put a comment next to each declaration if each one is on its
1273 Section 32.5. For aspects of 1274 data use, see Chapters 10	own line. It's easier to modify declarations because each declaration is self-
1274 through 13.	contained. It's easier to find specific variables because you can scan a single col-
	umn rather than reading each line. It's easier to find and fix syntax errors be-
1276	cause the line number the compiler gives you has only one declaration on it.
1277	Quickly—in the data declaration in Listing 31-50, what type of variable is
1278	currentBottom?
1279	Listing 31-50. C++ example of crowding more than one variable declara-
1280	tion onto a line.
1281 CODING HORROR	<pre>int rowIndex, columnIdx; Color previousColor, currentColor, nextColor; Point</pre>
1282	previousTop, previousBottom, currentTop, currentBottom, nextTop, nextBottom; Font
1283	<pre>previousTypeface, currentTypeface, nextTypeface; Color choices[NUM_COLORS];</pre>
1284	This is an extreme example. But it is not too far removed from a much more
1285	common style shown in Listing 31-51:
1286	Listing 31-51. C++ example of crowding more than one variable declara-
1287	tion onto a line.
1288 CODING HORROR	int rowIndex, columnIdx;
1289	Color previousColor, currentColor, nextColor;
1290	Point previousTop, previousBottom, currentTop, currentBottom, nextTop, nextBottom;
1291	Font previousTypeface, currentTypeface, nextTypeface;
1291 1292	Font previousTypeface, currentTypeface, nextTypeface; Color choices[NUM_COLORS];
1292	Color choices[NUM_COLORS];
1292 1293	Color choices[NUM_COLORS]; This is not an uncommon style of declaring variables, and the variable is still

In this case, the "clever" version carries an 11 percent speed penalty, which

off striving for clarity and correctness first, performance second.

makes it look a lot less clever. The results vary from compiler to compiler, but in

general they suggest that until you've measured performance gains, you're better

Now, what is *nextColor*'s type in Listing 31-52?

1297	Listing 31-52. C++ example of readability achieved by putting only one
1298	variable declaration on each line.
1299	int rowIndex;
1300	int columnIdx;
1301	Color previousColor;
1302	Color currentColor;
1303	Color nextColor;
1304	Point previousTop;
1305	Point previousBottom;
1306	Point currentTop;
1307	Point currentBottom;
1308	Point nextTop;
1309	Point nextBottom;
1310	Font previousTypeface;
1311	Font currentTypeface;
1312	Font nextTypeface;
1313	Color choices[NUM_COLORS];
1314	The variable <i>nextColor</i> was probably easier to find than <i>nextTypeface</i> was in
1315	Listing 31-51. This style is characterized by one declaration per line and a com-
1316	plete declaration including the variable type on each line.
1317	Admittedly, this style chews up a lot of screen space—20 lines instead of the 3 in
1318	the first example, although those 3 lines were pretty ugly. I can't point to any
1319	studies that show that this style leads to fewer bugs or greater comprehension. If
1320	Sally Programmer, Jr. asked me to review her code, however, and her data decla-
1321	rations looked like the first example, I'd say, "No way-too hard to read." If
1322	they looked like the second example, I'd say, "Uhmaybe I'll get back to you."
1323	If they looked like the final example, I would say, "Certainly—it's a pleasure."
1324	Declare variables close to where they're first used
1325	A style that's preferable to declaring all variables in a big block is to declare
1326	each variable close to where it's first used. This reduces "span" and "live time"
1327	and facilitates refactoring code into smaller routines when necessary. For more
1328	details, see "Keep Variables Live for As Short a Time As Possible" in Section
1329	10.4.
1330	Order declarations sensibly
1331	In the example above, the declarations are grouped by types. Grouping by types
1332	is usually sensible since variables of the same type tend to be used in related op-
1333	erations. In other cases, you might choose to order them alphabetically by vari-
1334	able name. Although alphabetical ordering has many advocates, my feeling is
1335	that it's too much work for what it's worth. If your list of variables is so long that
1336	alphabetical ordering helps, your routine is probably too big. Break it up so that
	you have smaller routines with fewer variables.
1337	you have smaller fournes with lewer variables.

1338	In C++, put the asterisk next to the variable name in pointer declarations
1339	or declare pointer types
1340	It's common to see pointer declarations that put the asterisk next to the type, as
1341	in Listing 31-53:
1342	Listing 31-53. C++ example of asterisks in pointer declarations.
1342	EmployeeList* employees;
1343	File* inputFile;
1345	The problem with putting the asterisk next to the type name rather than the vari-
1345	able name is that, when you put more than one declaration on a line, the asterisk
1347	will apply only to the first variable even though the visual formatting suggests it
1348	applies to all variables on the line.
1349	You can avoid this problem by putting the asterisk next to the variable name
1350	rather than the type name, as in Listing 31-54:
1051	Listing 24 54 Company of using actorists in a sinter declarations
1351	Listing 31-54. C++ example of using asterisks in pointer declarations.
1352	EmployeeList *employees;
1353	File *inputFile; This approach has the weathers of successfue that the estemistric part of the veri
1354	This approach has the weakness of suggesting that the asterisk is part of the vari-
1355	able name, which it isn't. The variable can be used either with or without the
1356	asterisk.
1357	The best approach is to declare a type for the pointer and use that instead. An
1358	example is shown in Listing 31-55:
1359	Listing 31-55. C++ example of good uses of a pointer type in declara-
1360	tions.
1361	EmployeeListPointer employees;
1362	FilePointer inputFile;
	The particular problem addressed by this approach can be solved either by re-
1363	
1364	quiring all pointers to be declared using pointer types, as shown in Listing 31-55,
1365	or by requiring no more than one variable declaration per line. Be sure to choose
1366	at least one of these solutions!

1368 CROSS-REFERENCE For

1369 details on other aspects of

1370 comments, see Chapter 32, "Self-Documenting Code."

31.6 Laying Out Comments

Comments done well can greatly enhance a program's readability. Comments done poorly can actually hurt it. The layout of comments plays a large role in whether they help or hinder readability.

1371	Indent a comment with its corresponding code
1372	Visual indentation is a valuable aid to understanding a program's logical struc-
1373	ture, and good comments don't interfere with the visual indentation. For exam-
1374	ple, what is the logical structure of the routine shown in Listing 31-56?
1375	Listing 31-56. Visual Basic example of poorly indented comments.
1376 CODING HORROR	For transactionId = 1 To totalTransactions
1377	' get transaction data
1378	GetTransactionType(transactionType)
1379	GetTransactionAmount(transactionAmount)
1380	
1381	' process transaction based on transaction type
1382	If transactionType = Transaction_Sale Then
1383	AcceptCustomerSale(transactionAmount)
1384	
1385	Else
1386	If transactionType = Transaction_CustomerReturn Then
1387	
1388	' either process return automatically or get manager approval, if required
1389	<pre>If transactionAmount >= MANAGER_APPROVAL_LEVEL Then</pre>
1390	
1391	' try to get manager approval and then accept or reject the return
1392	' based on whether approval is granted
1393	GetMgrApproval(isTransactionApproved)
1394	If (isTransactionApproved) Then
1395	AcceptCustomerReturn(transactionAmount)
1396	Else
1397	RejectCustomerReturn(transactionAmount)
1398	End If
1399	Else
1400	
1401	' manager approval not required, so accept return
1402	AcceptCustomerReturn(transactionAmount)
1403	End If
1404	End If
1405	End If
1406	Next
1407	In this example you don't get much of a clue to the logical structure because the
1408	comments completely obscure the visual indentation of the code. You might find
1409	it hard to believe that anyone ever makes a conscious decision to use such an
1410	indentation style, but I've seen it in professional programs and know of at least
1411	one textbook that recommends it.
1412	The code shown in Listing 31-57 is exactly the same as in Listing 31-56, except
1413	for the indentation of the comments.

1414	Listing 31-57. Visual Basic example of nicely indented comments.
1415	For transactionId = 1 To totalTransactions
1416	' get transaction data
1417	GetTransactionType(transactionType)
1418	GetTransactionAmount(transactionAmount)
1419	
1420	' process transaction based on transaction type
1421	If transactionType = Transaction_Sale Then
1422	AcceptCustomerSale(transactionAmount)
1423	
1424	Else
1425	<pre>If transactionType = Transaction_CustomerReturn Then</pre>
1426	
1427	' either process return automatically or get manager approval, if required
1428	If transactionAmount >= MANAGER_APPROVAL_LEVEL Then
1429	
1430	' try to get manager approval and then accept or reject the return
1431	' based on whether approval is granted
1432	GetMgrApproval(isTransactionApproved)
1433	If (isTransactionApproved) Then
1434	AcceptCustomerReturn(transactionAmount)
1435	Else
1436	RejectCustomerReturn(transactionAmount)
1437	End If
1438	Else
1439	' manager approval not required, so accept return
1440	AcceptCustomerReturn(transactionAmount)
1441	End If
1442	End If
1443	End If
1444	Next
1445	In Listing 31-57, the logical structure is more apparent. One study of the effec-
1446	tiveness of commenting found that the benefit of having comments was not con-
1447	clusive, and the author speculated that it was because they "disrupt visual scan-
1448	ning of the program" (Shneiderman 1980). From these examples, it's obvious
1449	that the style of commenting strongly influences whether comments are disrup-
1450	tive.
1451	Set off each comment with at least one blank line
1452	If someone is trying to get an overview of your program, the most effective way
1453	to do it is to read the comments without reading the code. Setting comments off
1454	with blank lines helps a reader scan the code. An example is shown in Listing
1455	31-58:
1456	Listing 31-58. Java example of setting off a comment with a blank line.
1457	// comment zero

1458	CodeStatementZero;
1459	CodeStatementOne;
1460	
1461	// comment one
1462	CodeStatementTwo;
1463	CodeStatementThree;
1464	Some people use a blank line both before and after the comment. Two blanks use
1465	more display space, but some people think the code looks better than with just
1466	one. An example is shown in Listing 31-59:
1467	Listing 31-59. Java example of setting off a comment with two blank
1468	lines.
1469	
1470	// comment zero
1471	
1472	CodeStatementZero;
1473	CodeStatementOne;
1474	
1475	// comment one
1476	
1477	CodeStatementTwo;
1478	CodeStatementThree;
1479	Unless your display space is at a premium, this is a purely aesthetic judgment
1480	and you can make it accordingly. In this, as in many other areas, the fact that a
1481	convention exists is more important than the convention's specific details.

1482

1494

31.7 Laying Out Routines

Routines are composed of individual statements, data, control structures, comments—all the things discussed in the other parts of the chapter. This section provides layout guidelines unique to routines.

Use blank lines to separate parts of a routine

Use blank lines between the routine header, its data and named-constant declarations (if any), and its body.

Use standard indentation for routine arguments

The options with routine-header layout are about the same as they are in a lot of other areas of layout: no conscious layout, endline layout, or standard indentation. As in most other cases, standard indentation does better in terms of accuracy, consistency, readability, and modifiability.

Listing 31-60 shows two examples of routine headers with no conscious layout:

1495	Listing 31-60. C++ examples of routine headers with no conscious lay-		
1496	out.		
1497	<pre>bool ReadEmployeeData(int maxEmployees,EmployeeList *employees,</pre>		
1498	<pre>EmployeeFile *inputFile,int *employeeCount,bool *isInputError)</pre>		
1499			
1500			
1501	<pre>void InsertionSort(SortArray data,int firstElement,int lastElement)</pre>		
1502	These routine headers are purely utilitarian. The computer can read them as well		
1503	as it can read headers in any other format, but they cause trouble for humans.		
1504	Without a conscious effort to make the headers hard to read, how could they be		
1505	any worse?		
	•		
1506	The second approach in routine-header layout is the endline layout, which usu-		
1507	ally works all right. Listing 31-61 shows the same routine headers reformatted:		
1508	Listing 31-61. C++ example of routine headers with mediocre endline		
1509	layout.		
1510	bool ReadEmployeeData(int maxEmployees,		
1511	EmployeeList *employees,		
1512	EmployeeFile *inputFile,		
1513	int *employeeCount,		
1514	bool *isInputError)		
1515			
1516	void InsertionSort(SortArray data,		
1517	int firstElement,		
1518	int lastElement)		
1519 CROSS-REFERENCE For	The endline approach is neat and aesthetically appealing. The main problem is		
1520 more details on using routine	that it takes a lot of work to maintain, and styles that are hard to maintain aren't		
1521 parameters, see Section 7.5, "How to Use Routine Pa-	maintained. Suppose that the function name changes from <i>ReadEmployeeData()</i>		
1522 rameters."	to ReadNewEmployeeData(). That would throw the alignment of the first line off		
1523	from the alignment of the other four lines. You'd have to reformat the other four		
1524	lines of the parameter list to align with the new position of maxEmployees		
1525	caused by the longer function name. And you'd probably run out of space on the		
1526	right side since the elements are so far to the right already.		
1527	The examples shown in Listing 31-62, formatted using standard indentation, are		
1528	just as appealing aesthetically but take less work to maintain.		
1529	Listing 31-62. C++ example of routine headers with readable, maintain-		
1530	able standard indentation.		
1531	public bool ReadEmployeeData(
1532	int maxEmployees,		
1533	EmployeeList *employees,		
1534	EmployeeFile *inputFile,		
1535	int *employeeCount,		

1536		bool *isInputError
1537)
1538		
1539		
1540		public void InsertionSort(
1541		SortArray data,
1542		int firstElement,
1543		int lastElement
1544)
1545		This style holds up better under modification. If the routine name changes, the
1546		change has no effect on any of the parameters. If parameters are added or de-
1547		leted, only one line has to be modified—plus or minus a comma. The visual cues
1548		are similar to those in the indentation scheme for a loop or an <i>if</i> statement. Your
1549		eye doesn't have to scan different parts of the page for every individual routine
1550		to find meaningful information; it knows where the information is every time.
1551		This style translates to Visual Basic in a straightforward way, though it requires
1552		the use of line-continuation characters, as shown in Listing 31-63:
1553		Listing 31-63. Visual Basic example of routine headers with readable,
1554		maintainable standard indentation.
1555	Here's the "_" character used	Public Sub ReadEmployeeData (_

31.8 Laying Out Classes

Here are several guidelines for laying out code within a class. The next section contains guidelines for laying out code within a file.

Laying Out Class Interfaces

In laying out class interfaces, the convention is to present the class members in the following order:

- 1. Header comment that describes the class and provides any notes about the overall usage of the class
- 2. Constructors and destructors

1571		3. Public routines
1572		4. Protected routines
1573		5. Private routines and member data
1574		Laying Out Class Implementations
1575		Class implementations are generally laid out in this order:
1576		1. Header comment that describes the contents of the file the class is in
1577		2. Class data
1578		3. Public routines
1579		4. Protected routines
1580		5. Private routines
1581		If you have more than one class in a file, identify each class clearly
1582		Routines that are related should be grouped together into classes. A reader scan-
1583		ning your code should be able to tell easily which class is which. Identify each
1584		class clearly by using several blank lines between it and the classes next to it. A
1585		class is like a chapter in a book. In a book, you start each chapter on a new page
1586		and use big print for the chapter title. Emphasize the start of each class similarly.
1587		An example of separating classes is shown in Listing 31-64.
1588		Listing 31-64. C++ example of formatting the separation between
1589		classes.
1590	This is the last routine in a	<pre>// create a string identical to sourceString except that the</pre>
1591	class.	// blanks are replaced with underscores.
1592		<pre>void EditString::ConvertBlanks(</pre>
1593		char *sourceString,
1594		char *targetString
1595		
1596		Assert(strlen(sourceString) <= MAX_STRING_LENGTH);
1597 1598		Assert(sourceString != NULL);
1598		Assert(targetString != NULL); int charIndex = 0;
1600		do {
1601		<pre>if (sourceString[charIndex] == " ") {</pre>
1602		<pre>targetString[charIndex] = '_';</pre>
1603		}
1604		else {
1605		<pre>targetString[charIndex] = sourceString[charIndex];</pre>

```
1606
                                }
1607
                                charIndex++;
1608
                             } while sourceString[ charIndex ] != '\0';
1609
                          }
1610
1611
       The beginning of the new
1612
     class is marked with several
                           // MATHEMATICAL FUNCTIONS
     blank lines and the name of
1613
                           11
1614
                 the class.
                           // This class contains the program's mathematical functions.
1615
                           //-----
                                                              _____
1616
1617
                           // find the arithmetic maximum of arg1 and arg2
      This is the first routine in a
1618
                 new class.
                           int Math::Max( int arg1, int arg2 ) {
1619
                             if ( arg1 > arg2 ) {
1620
                                return arg1;
1621
                             }
1622
                             else {
1623
                                return arg2;
1624
                             }
1625
                          }
1626
1627
                           // find the arithmetic minimum of arg1 and arg2
1628
    This routine is separated from
1629
    the previous routine by blank
                           int Math::Min( int arg1, int arg2 ) {
1630
                 lines only.
                             if ( arg1 < arg2 ) {
1631
                                return arg1;
1632
                             }
1633
                             else {
1634
                                return arg2;
1635
                             }
1636
1637
                           Avoid overemphasizing comments within classes. If you mark every routine and
                           comment with a row of asterisks instead of blank lines, you'll have a hard time
1638
                           coming up with a device that effectively emphasizes the start of a new class. An
1639
                           example is shown in Listing 31-65.
1640
                           Listing 31-65. C++ example of overformatting a class.
1641
                                  *******
1642
                           1643
                           // MATHEMATICAL FUNCTIONS
1644
                           11
1645
1646
                           // This class contains the program//s mathematical functions.
1647
                           1648
1649
                           1650
```

1651	<pre>// find the arithmetic maximum of arg1 and arg2</pre>
1652	//*********************
1653	<pre>int Math::Max(int arg1, int arg2) {</pre>
1654	//*************************************
1655	if (arg1 > arg2) {
1656	return arg1;
1657	}
1658	else {
1659	return arg2;
1660	}
1661	}
1662	
1663	//*************************************
1664	<pre>// find the arithmetic maximum of arg1 and arg2</pre>
1665	//*************************************
1666	<pre>int Math::Min(int arg1, int arg2) {</pre>
1667	//*************************************
1668	if (arg1 < arg2) {
1669	return arg1;
1670	}
1671	else {
1672	return arg2;
1673	}
1674	}
1675	In this example, so many things are highlighted with asterisks that nothing is
1676	really emphasized. The program becomes a dense forest of asterisks. Although
1677	it's more an aesthetic than a technical judgment, in formatting, less is more.
1678	If you must separate parts of a program with long lines of special characters, de-
1679	velop a hierarchy of characters (from densest to lightest) instead of relying ex-
1680	clusively on asterisks. For example, use asterisks for class divisions, dashes for
1681	routine divisions, and blank lines for important comments. Refrain from putting
1682	two rows of asterisks or dashes together. An example is shown in Listing 31-66.
	······································
1683	Listing 31-66. C++ example of good formatting with restraint.
1684	//*************************************
1685	// MATHEMATICAL FUNCTIONS
1686	//
1687	// This class contains the program's mathematical functions.
1688	//*************************************

      pared to the line of asterisks
1692
    visually reinforces the fact that
                               //-----
      the routine is subordinate to
1693
                               int Math::Max( int arg1, int arg2 ) {
                    the class.
1694
                                  if (arg1 > arg2) {
1695
                                     return arg1;
1696
                                  }
1697
                                  else {
1698
                                     return arg2;
                                  }
1699
1700
                               }
1701
                               //-----
1702
1703
                               // find the arithmetic minimum of arg1 and arg2
                               //-----
1704
1705
                               int Math::Min( int arg1, int arg2 ) {
1706
                                  if (arg1 < arg2) {
1707
                                     return arg1;
1708
                                  }
1709
                                  else {
1710
                                     return arg2;
1711
                                  }
1712
                               }
                               This advice about how to identify multiple classes within a single file applies
1713
                               only when your language restricts the number of files you can use in a program.
1714
                               If you're using C++, Java, Visual Basic or other languages that support multiple
1715
                               source files, put only one class in each file unless you have a compelling reason
1716
1717
                               to do otherwise (such as including a few small classes that make up a single pat-
                               tern). Within a single class, however, you might still have subgroups of routines,
1718
                               and you can group them using techniques such as the ones shown here.
1719
```

Laying Out Files and Programs

Beyond the formatting techniques for routines is a larger formatting issue. How do you organize routines within a file, and how do you decide which routines to put in a file in the first place?

Put one class in one file

A file isn't just a bucket that holds some code. If your language allows it, a file should hold a collection of routines that supports one and only one purpose. A file reinforces the idea that a collection of routines are in the same class.

1728 CROSS-REFERENCE For 1729 details on the differences	All the routines within a file make up the class. The class might be one that the program really recognizes as such, or it might be just a logical entity that you've
1730 between classes and routines and how to make a collection	created as part of your design.
of routines into a class, see 1731 Chapter 6, "Working	Classes are a semantic language concept. Files are a physical operating-system
1732 Classes."	concept. The correspondence between classes and files is coincidental and con-
1733	tinues to weaken over time as more environments support putting code into data-
1734	bases or otherwise obscuring the relationship between routines, classes, and files.
1735	Give the file a name related to the class name
1736	Most projects have a one-to-one correspondence between class names and file
1737	names. A class named CustomerAccount would have files named
1738	CustomerAccount.cpp and CustomerAccount.h, for example.
1739	Separate routines within a file clearly
1740	Separate each routine from other routines with at least two blank lines. The blank
1741	lines are as effective as big rows of asterisks or dashes, and they're a lot easier to
1742	type and maintain. Use two or three to produce a visual difference between blank
1743	lines that are part of a routine and blank lines that separate routines. An example
1744	is shown in Listing 31-67:
1745	Listing 31-67. Visual Basic example of using blank lines between rou-
1746	tines.

------	----

1769	Sequence routines alphabetically	
1770	An alternative to grouping related routines in a file is to put them in alphabetical	
1771	order. If you can't break a program up into classes or if your editor doesn't allow you to find functions easily, the alphabetical approach can save search time.	
1772	you to find functions easily, the alphabetical approach can save search time.	
1773	In C++, order the source file carefully	
1774	Here's the standard order of source-file contents in C++:	
1775	File-description comment	
1776	<i>#include</i> files	
1777	Constant definitions	
1778	Enums	
1779	Macro function definitions	
1780	Type definitions	
1781	Global variables and functions imported	
1782	Global variables and functions exported	
1783	Variables and functions that are private to the file	
1784	Classes	
CC2E.COM/3194 1785	CHECKLIST: Layout	
1786	General	
1787	□ Is formatting done primarily to illuminate the logical structure of the code?	
1788	□ Can the formatting scheme be used consistently?	
1789	Does the formatting scheme result in code that's easy to maintain?	
1790	Does the formatting scheme improve code readability?	
1791	Control Structures	
1792	Does the code avoid doubly indented <i>begin-end</i> or {} pairs?	
1793	□ Are sequential blocks separated from each other with blank lines?	
1794	□ Are complicated expressions formatted for readability?	
1795	□ Are single-statement blocks formatted consistently?	
1796	□ Are <i>case</i> statements formatted in a way that's consistent with the formatting	
1797	of other control structures?	

1798	□ Have <i>gotos</i> been formatted in a way that makes their use obvious?
1799	Individual Statements
1800	□ Is white space used to make logical expressions, array references, and rou-
1801	tine arguments readable?
1802	Do incomplete statements end the line in a way that's obviously incorrect?
1803	□ Are continuation lines indented the standard indentation amount?
1804	Does each line contain at most one statement?
1805	□ Is each statement written without side effects?
1806	□ Is there at most one data declaration per line?
1807	Comments
1808	Are the comments indented the same number of spaces as the code they
1809	comment?
1810	□ Is the commenting style easy to maintain?
1811	Routines
1812 1813	□ Are the arguments to each routine formatted so that each argument is easy to read, modify, and comment?
1814	□ Are blank lines used to separate parts of a routine?
1815	Classes, Files and Programs
1816	□ Is there a one-to-one relationship between classes and files for most classes
1817	and files?
1818	□ If a file does contain multiple classes, are all the routines in each class
1819	grouped together and is the class clearly identified?
1820	Are routines within a file clearly separated with blank lines?
1821	□ In lieu of a stronger organizing principle, are all routines in alphabetical se-
1822	quence?

1825	Most programming textbooks say a few words about layout and style, but thor-

Most programming textbooks say a few words about layout and style, but thorough discussions of programming style are rare; discussions of layout are rarer still. The following books talk about layout and programming style.

Kernighan, Brian W. and Rob Pike. *The Practice of Programming*, Reading, Mass.: Addison Wesley, 1999. Chapter 1 of this book discusses programming style focusing on C and C++.

1830

1831 1832	Vermeulen, Allan, et al. <i>The Elements of Java Style</i> , Cambridge University Press, 2000.
1833 1834	Bumgardner, Greg, Andrew Gray, and Trevor Misfeldt, 2004. <i>The Elements of</i> $C++$ <i>Style</i> , Cambridge University Press, 2004.
1835 1836 1837	Kernighan, Brian W., and P. J. Plauger. <i>The Elements of Programming Style</i> , 2d ed. New York: McGraw-Hill, 1978. This is the classic book on programming style—the first in the genre of programming-style books.
1838 1839	For a substantially different approach to readability, see the discussion of Donald Knuth's "literate programming" listed below.
1840 1841 1842 1843 1844 1845 1846	Knuth, Donald E. <i>Literate Programming</i> . Cambridge University Press, 2001. This is a collection of papers describing the "literate programming" approach of combining a programming language and a documentation language. Knuth has been writing about the virtues of literate programming for about 20 years, and in spite of his strong claim to the title Best Programmer on the Planet, literate pro- gramming isn't catching on. Read some of his code to form your own conclu- sions about the reason.
1847	Key Points
1847 1848 1849 1850	 Key Points The first priority of visual layout is to illuminate the logical organization of the code. Criteria used to assess whether the priority is achieved include accuracy, consistency, readability, and maintainability.
1848 1849	• The first priority of visual layout is to illuminate the logical organization of the code. Criteria used to assess whether the priority is achieved include ac-
1848 1849 1850 1851 1852	 The first priority of visual layout is to illuminate the logical organization of the code. Criteria used to assess whether the priority is achieved include accuracy, consistency, readability, and maintainability. Looking good is secondary to the other criteria—a distant second. If the other criteria are met and the underlying code is good, however, the layout
1848 1849 1850 1851 1852 1853 1854 1855 1856	 The first priority of visual layout is to illuminate the logical organization of the code. Criteria used to assess whether the priority is achieved include accuracy, consistency, readability, and maintainability. Looking good is secondary to the other criteria—a distant second. If the other criteria are met and the underlying code is good, however, the layout will look fine. Visual Basic has pure blocks and the conventional practice in Java is to use pure block style, so you can use a pure-block layout if you program in those languages. In C++, either pure-block emulation or <i>begin-end</i> block bounda-
